FUNCTION DESCRIPTION

The MS31860T is a eight-channel low-side driver, which has overcurrent protection and open-circuit/short-circuit load detection functions. Internal integrated high-side body diode can be used to drive unipolar stepper motor, DC motor, relay, solenoid or other loads.

The MS31860T can provide up to 180mA duration output current for each channel when eight channels are all enabled. When single channel is enabled, 560mA duration output current is available. Refer to current capacity table for details

The MS31860T provides one serial interface to control output driver, configure internal setting register and read the fault state of each channel. Multiple MS31860Ts can adopt daisy chain to connect together and use same one serial interface. On addition, the energizing time and PWM duty cycle holding are configured via serial interface. Compared with traditional all-enabled solution, these functions are used to realize lower operating temperature.

The MS31860T provides perfect protection functions: overcurrent protection, short-circuit protection, undervoltage lockout and thermal shutdown. The MS31860T can diagnose open-circuit load condition. The fault information of each channel is read by serial interface and indicated by one external fault pin.

1. Recommended Output Current

The output current capacity of the MS31860T depends on some factors, including ambient temperature, maximum surface temperature, output duty cycle. Recommended output currents are as follows:

Recommended Output Current	
Configuration	Output Current Capacity
Enable 1 Output	566mA
Enable 2 Outputs	400mA
Enable 4 Outputs	283mA
Enable 8 Outputs	200mA

2. Daisy Chain

The MS31860T can adopt daisy chain and control two or multiple chips through serial interface. Previous DOUT pin is as next DIN pin input, other interfaces are used in common. Data is input from the first DIN and read from last DOUT as follows.

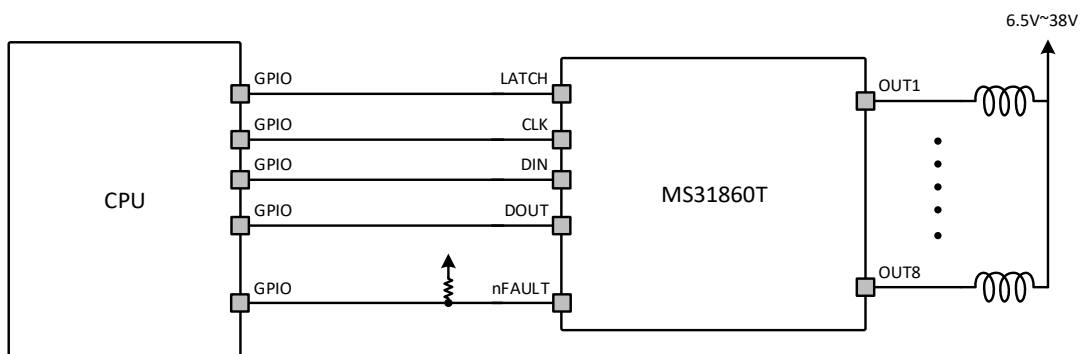

Figure 1. Single MS31860T Connection

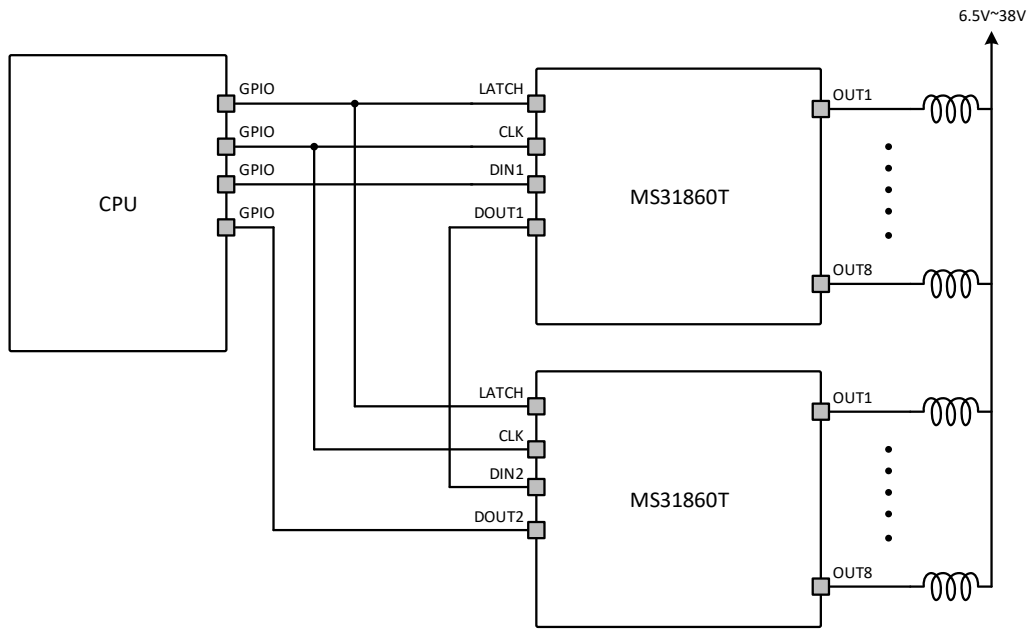

Figure 2. Multiple MS31860Ts Daisy Chain

3. Protection Circuit

The MS31860T has protection functions: undervoltage lockout (UVLO), overcurrent protection (OCP) and overtemperature protection (OTP). When these functions are triggered, shutdown operation is triggered to protect chip and motor.

3.1 OCP

When output current exceeds OCP trigger level, corresponding output channel is off. nFAULT pin is pulled down and OCP flag bit of fault register is set to 1.

When corresponding channel is off by register or write into fault reset command, fault flag would be cleared. And nFAULT pin is released and OCP flag bit is cleared.

3.2 Open-circuit Detection

When output is off, there is a 30 μ A pull-down current. If pin voltage is detected to be less than 1.2V at this time, it is judged as open-circuit load condition. nFAULT pin is set to low-level and open-circuit detection bit is set in the fault register.

When setting register enables corresponding channel, fault bit would be cleared. Or the fault indication is cleared by fault reset command.

3.3 OTP

When chip temperature exceeds temperature limit, OTP would be triggered. All outputs are disabled and nFAULT pin outputs low-level.

If chip temperature falls to normal, the fault would be cleared automatically and channel would recover operation.

3.4 UVLO

When VM pin voltage is less than undervoltage lockout threshold, all channels of the MS31860T are disabled and internal logic is reset. When VM rise to above ULVO, the MS31860T will recover normal operation. nFAULT pin is not pulled down when undervoltage is triggered.

3.5 Digital Noise Filtering

Each digital pin input of the MS31860T all has filtering circuit to ensure that data is not interfered and allow daisy chain to perform safely. If there is no input filter, output state will be effected by input noise or enter uncertain state. The digital input filter is realized by capacitor, which could filter needless noise frequency signal and ensure high-speed serial interface communication.

4. Function Mode Description

4.1 Internal Register

The MS31860T is controlled by SPI, including three groups of registers: data register, control register and fault register.

In default condition, the MS31860T can write into data register group and read from fault register group. Read and write commands of other register groups need some special commands to operate.

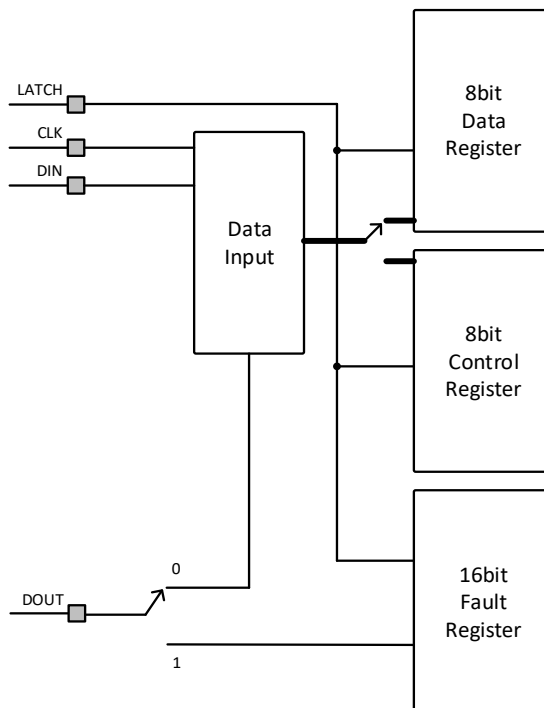

Figure 3. Register Overview

4.2 Basic Function

In the condition without any configuration, 8bit shift register shifts data into data register group and data is output through daisy chain. At this time, serial input data will directly control FET.

4.4 Special Command

In order to improve efficiency, the MS31860T has some special commands to read from and write into corresponding register, including five special commands. These commands need CLK interface and LATCH interface.

Above figure is PWM start command, referring to following table and above diagram. The MS31860T has five special commands.

Special Command	Part 1	Part 2	Part 3	Part 4

4.5.1 Data Register Group Function

In default condition, 8bit data input directly controls corresponding 8bit data in data register group. However, data register group directly corresponds to the states of eight output channels. In other words, 8bit data of SPI data input would directly control on-off of eight FETs.

4.5.2 Write Data Register Group

Because the MS31860T has daisy chain function, data can be continuously input. On the clock rising edge, external data would be serially input into data input and enter into register group on the rising edge of LATCH.
